CS 221: Section 2

Learning with Sequential Inputs/Outputs

...

Basics of Recurrent Neural Networks

Autumn 2017 Course Staff

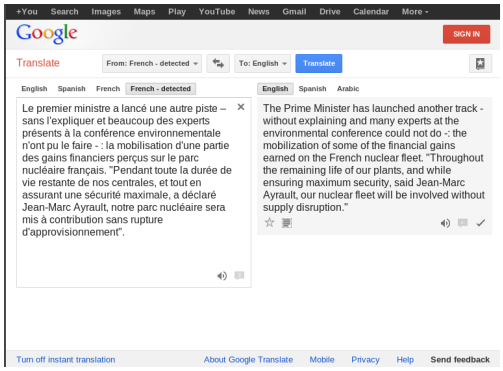
Outline

Outline

Medical Diagnosis

Input (x_t): medical history
Output (y_t): next emergency department visit

Text Translation

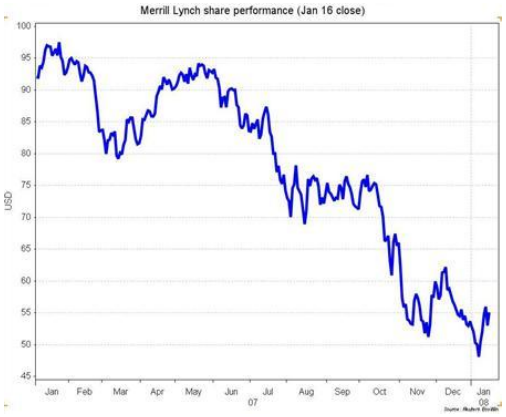


Input (x_t): French words in sentence
Output (y_t): translated English words

Image Captioning

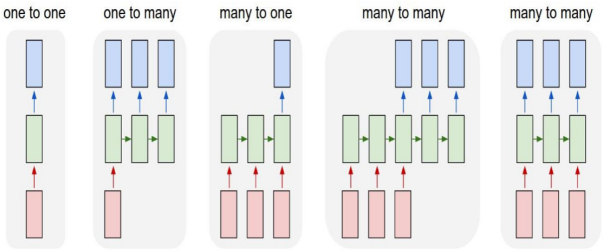
Input: image
Output: sentence of words

Stock Prediction



Input (x_t): historical stock prices
Output (y_t): stock price today

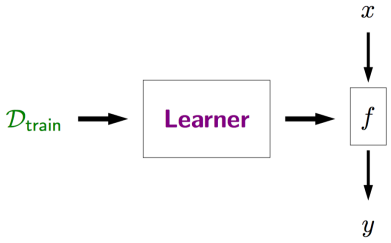
Sequences of Data



Adapted from Fei-Fei Li's CS 231N slides.

Outline

ML Framework



1. Obtain data $\mathcal{D}_{\text{train}}$.
2. Model: choose f to capture relationship between x and y.
3. Loss: specify a loss which tells how right or wrong your prediction is
4. Optimize: run gradient descent to find the best set of weights for your model

Developing a Stock Price Model

Goal: predict what the stock price will be today.

Idea: stock price today depends on prices in the past.

Data: Let x_t be the price on day t. We collect x_t from August, 2016 to August, 2017. Let y_t be the predicted price for day t.

Developing a Stock Price Model

Model: assume a linear relationship.

$$y_t = w_0 + w_1 x_{t-1} + w_2 x_{t-2} + w_3 x_{t-3}$$

In terms of the notation from lecture, we have

$$y_t = w^\top \phi_t, \qquad \phi_t = \left[1, x_{t-1}, x_{t-2}, x_{t-3}\right]^\top$$

Loss: squared loss between predicted and actual stock price.

$$L(x_t, y_t) = (x_t - y_t)^2 = (x_t - w^\top \phi_t)^2$$

Initial Stock Price Model

Benefits

- Training: just ordinary least squares [linear regression].
- Interpretability: linear combination of features.

Problems

- Scalability: We have to manually specify the number of days in the past to include as features.
- Features: hard to specify complex relation between past prices using linear model. For example, want to use $\mathbb{1}\{x_{t-4} - x_{t-5}\}$.

Long Past

Can we repackage the model to keep track of the history more easily?

Let's track h_t as our knowledge to predict time t. Suppose we set

$$h_t = ah_{t-1} + bx_{t-1}$$
$$h_{t-1} = ah_{t-2} + bx_{t-2}$$
$$\vdots$$

If we do this cleverly, we can have h_t account for all past information!

Adding Non-Linearity

Let's model a more complex relationship b/w the present and past.

Add some non-linear function; examples:

- sigmoid [logistic unit from lecture]
- relu [rectified linear unit]

We end up with:

$$h_t = f_{\text{nonlinear}}(ah_{t-1} + bx_{t-1})$$
$$y_t = g_{\text{nonlinear}}(ch_t)$$

Outline

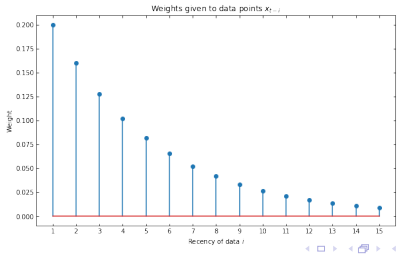
Example RNN Model

Let's model stock price as a weighted moving average.

$$h_t = f(h_{t-1}, x_{t-1}) \qquad h_t = (1-\alpha)h_{t-1} + \alpha x_{t-1}$$
$$y_t = g(h_t) \qquad y_t = h_t$$

Why is this a reasonable model? If we expand it out, we find

$$y_t = h_t = \alpha x_{t-1} + \alpha(1-\alpha)x_{t-2} + \alpha(1-\alpha)^2 x_{t-3} + \dots$$



Running forward and backward

Let's model stock price as a weighted moving average.

$$h_t = f(h_{t-1}, x_{t-1}) \qquad h_t = (1-\alpha)h_{t-1} + \alpha x_{t-1}$$
$$y_t = g(h_t) \qquad y_t = h_t$$

Suppose we're given $x = \begin{bmatrix}10 & 12 & 8 & 12\end{bmatrix}^\top$, and $\alpha = 0.2$.

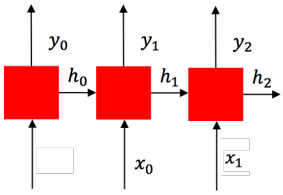
Basics of RNNs

We've covered a specific case of the more general RNN:



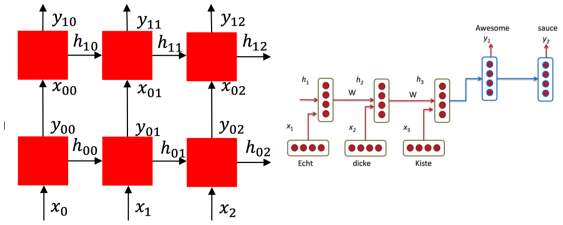
Adapted from John Canny's CS 294-129 slides.

So: RNN is neural network with recurrent feature over time.

$$h_t = f(h_{t-1}, x_{t-1})$$
$$y_t = g(h_t)$$

Expanding RNNs

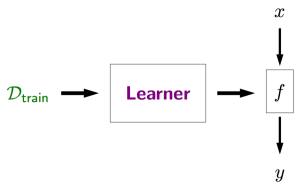
It's common to stack layers to train higher-level features. You can also have an input RNN (encoder) and an output RNN (decoder).



Adapted from John Canny's CS 294-129 slides and Stanford's CS 224N slides.

ML Framework

Takeaway. An RNN is just another choice of how we want to capture the relationship between X and Y! It can be combined with other RNN's or other models like a lego piece.



1. Obtain data $\mathcal{D}_{\text{train}}$.
2. Model: choose f to capture relationship between x and y.
3. Loss: specify a loss which tells how right or wrong your prediction is
4. Optimize: run gradient descent to find the best set of weights for your model
